Conservation issues

- Common dolphin is believed to have declined in the Mediterranean
- ACCOBAMS has developed a Conservation Plan
- Effective conservation depends on our understanding of the ecology
- The Alborán Sea is its most important remaining habitat – constitutes a vital source of information

Source: Bearzi et al. 2003

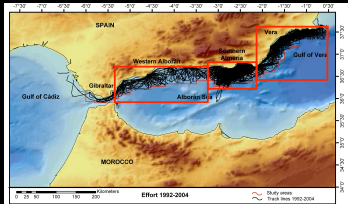

Methods

- Line transect data (1992 – 2004)
- Data on environmental variables

Study area: 19,189 sq km

Effort: 37,385 km

Sightings: 738 groups

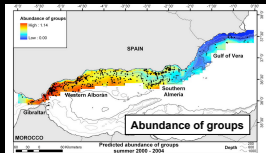

Effort 1992-2004

Methods

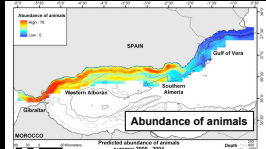

- **Distribution and abundance:**
Spatial modelling (GAMs) was used using 'extrinsic' (environmental) variables (e.g. depth, slope, sea surface temperature, chlorophyll concentration, distance from coast, distance from the shelf edge)
Two steps were used: - modelling abundance of groups (probability of detection combined with spatial analysis) - abundance of animals
- modelling group sizes
- **Differences were examined among:**
 - a) Sub-areas
 - Western Alborán
 - Southern Almería
 - Gulf of Vera
 - b) Groups of years
 - c) Seasons
 - summer: June to September
 - winter: October to May
 - d) 'Intrinsic' variables
 - behaviour
 - presence of calves
 - interspecies agregations

Results: abundance

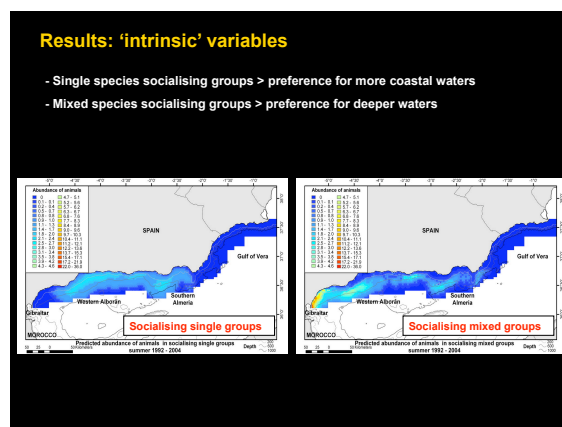

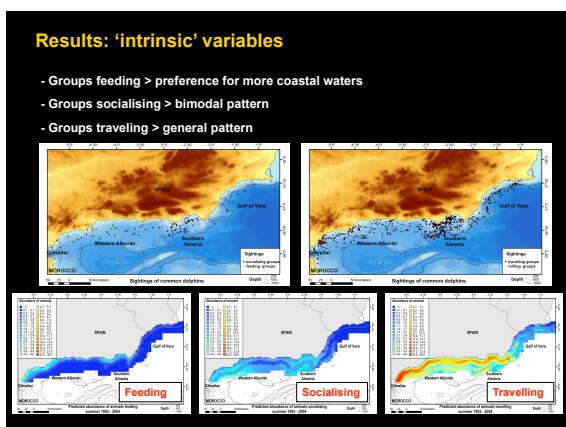

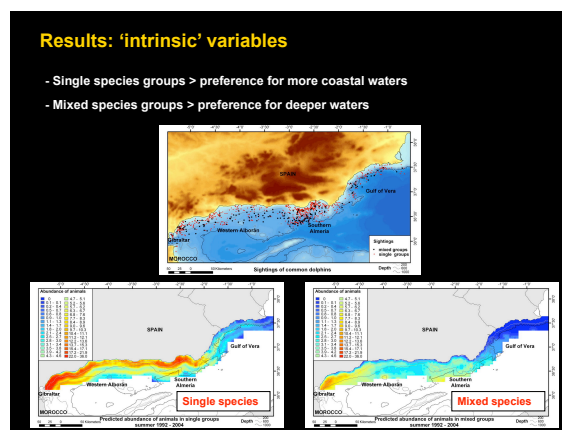

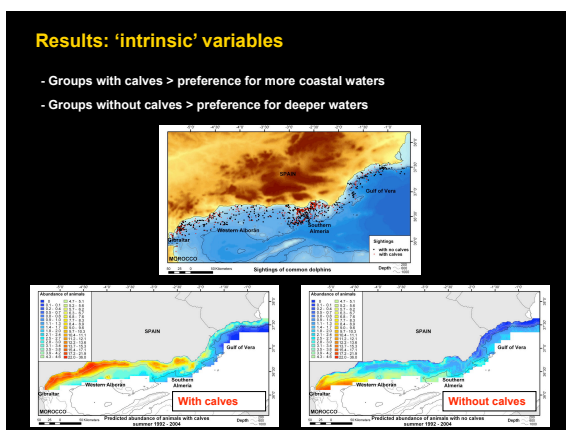

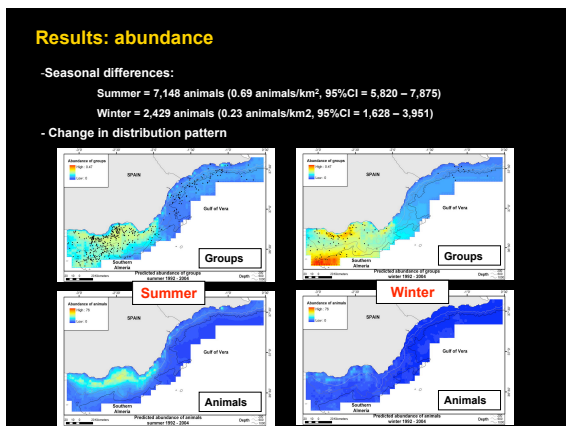

- **Total abundance:**
19,429 animals (density = 1.01 animals/km²)
95%CI = 15,277 - 22,804
CV = 0.11 – 0.18
- **Geographical differences:**
W. Alborán = 1.55 animals/km²
Almería = 0.97 animals/km²
G. of Vera = 0.14 animals/km²
- **Bimodal distribution pattern**

Abundance of groups

Abundance of animals

Conclusions

1. Estimated abundance fairly stable in the northern Alborán Sea since 1992

- In contrast with the decline in the rest of the Mediterranean
- Despite reported by-catch rate Moroccan driftnets in southern Alborán Sea (approx. 1,500 per year)

Conclusions

2. There is a significant drop in density in the Gulf of Vera since 1996

- Exponential growth of aquaculture since mid 1990s
- Catches of round sardinella (*Sardinella aurita*) to feed the fish have also increased exponentially
- This may have led to a reduction in prey availability
- It could also be due to similar reasons as for the rest of the Mediterranean

Conclusions

3. Shelf edge areas, especially off Malaga and Almeria, are preferred habitats, particularly when feeding and with calves

- This is also the area with the strongest impact from human activities
- This kind of information could lead to specific management measures for those areas

Conclusions

4. Introducing 'intrinsic' factors leads to a clearer picture of habitat use

- Improves our understanding of the ecology of the species
- Should also lead to more effective conservation
- Outcomes are easy for administrators
